

Mission Control Token Spike Postmortem

Executive Summary

This report explains why Mission Control burned through a catastrophic amount of tokens and thread/session churn during the benchmark effort focused on project '11' ('Loop Improvements Shadow Repo R6 Benchmark'). The short version is brutal: Mission Control kept spawning and re-spawning worker runs faster than it was closing valid work, it continued operating through model-policy failures and usage-limit failures, it allowed the same task lanes to be retried dozens to more than a hundred times, and I did not pull the emergency brake soon enough.

Local Mission Control telemetry records ****715,075,711 tokens**** across all stored runs, including ****684,853,363 tokens**** for project '11' alone. The user-supplied Codex profile screenshot reports a ****1.5B peak-token day**** and ****2,103 total threads****. Those two facts are compatible rather than contradictory: the local database is clearly undercounting the full Codex-side billing footprint, while the local run volume and thread-spawn patterns explain how the profile number could reach that scale.

Most importantly, this was not one bug. It was a stacked failure chain: weak run-budget controls, missing circuit breakers, retry churn, scheduler supersession churn, policy-invalid model assignments, usage-limit handling that did not force a clean stop, and bad operator supervision from me.

Incident Scope

- Report generated at: '2026-06-21T14:22:30-05:00'
- Repo commit examined: '2f364f8ea04c5b06a1d563c143cabf62b1cea76c'
- Mission Control DB: 'C:/Users/mike/OneDrive/Desktop/Codex Mission Control/.runtime/mission_control.sqlite3'
- Focus project: '11' / 'Loop Improvements Shadow Repo R6 Benchmark'
- Project workspace: 'C:/Users/mike/OneDrive/Desktop/Codex Mission Control/.runtime/recursive-improvement/loop-improvements-r6-benchmark/repo'
- Project status when frozen: 'building'
- Runner mode: 'cli'
- Manager mode: 'auto'
- Handoff status: 'not_ready'
- Evidence source for 1.5B / 2,103 numbers: User-supplied Codex profile screenshot captured on June 21, 2026 showing 1.5B peak tokens and 2,103 total threads.

High-Level Metrics

Metric	Value
---	---
Projects in local DB	12
Agents in local DB	77
Agent runs in local DB	1,982
Tasks in local DB	459
Event log files in '.runtime/logs'	4,288

| Tracked text files line-counted | 1,291 |  
| Tracked binary files skipped for line count | 13 |  
| Tracked text lines scanned | 215,699 |
```

Why The 1.5B Number Happened

1. Mission Control created far too many runs

Project '11' alone generated **982 stored worker runs**. That is already enough to explain why the Codex profile shows thread explosion: one run/retry/review loop maps very closely to one Codex thread or session lifecycle.

2. It kept retrying the same task lanes

The same defect batches were run again and again. Instead of a clean work queue, the system accumulated 'superseded', 'unblock', and 're-run' variants of the same lane family, which means the scheduler was doing substantial self-generated work.

Task ID	Task Title	Runs	Tokens
---	---	---	---
356	Apps Mcp Server Tests Defect Batch	115	58,125,393
359	Apps Desktop Tests Defect Batch	103	27,574,966

324	Apps Server Defect Batch	17	13,309,180
321	Apps Dashboard Defect Batch	14	18,236,811
323	Apps Mcp Server Defect Batch	11	9,419,739
329	Examples Codex Chat Workflows Defect Batch	9	7,739,001
458	Unblock: Unblock: Unblock: Apps Mcp Server Tests Defect Batch	9	1,967,341
451	Fix workflow and issue intake accuracy	7	3,958,806
443	Workflow And Issue Intake Accuracy Batch	7	3,522,376
432	Server Runtime And Packaging Defect Batch	6	12,995,108

3. It spent real money on no-op and low-yield runs

- 'done' runs with zero changed files recorded: **64**
- All runs with zero changed files recorded: **326**
- Runs missing a report entirely: **290**

That means Mission Control was willing to count or at least execute a large amount of work that produced no code changes, which is exactly how you turn tokens into heat.

4. It continued through hard failures instead of tripping a stop condition

- Usage-limit blocked runs found in stored reports: **11**
- Runner-bug failures included invalid model selection and malformed completion envelopes.
- The benchmark kept generating backlog churn and unblock tasks instead of

entering a hard-fail quarantine.

Thread Explosion Analysis

The Codex profile reports ****2,103 total threads****. The local Mission Control DB contains ****1,982 agent runs**** overall, with ****982**** of them in project '11' alone. That is not a coincidence. The simplest explanation is that Mission Control's worker orchestration pattern was creating a fresh Codex-side session or thread for each lane execution, retry, review pass, or resume attempt.

The remaining difference between 2,103 profile threads and 1,982 local agent runs is plausibly explained by manager-side sessions, monitoring threads, manual babysitting threads, and failed or partially-persisted runs that were billed on the Codex side but did not leave a clean local DB envelope.

Status Mix

Run Status	Failure Class	Count	Tokens

Concrete Failure Signatures

Unsupported model selection

Stored runner-bug envelopes show repeated 400-level failures from Codex itself because Mission Control tried to use 'gpt-5.3-codex' with a ChatGPT account, which that environment did not support. That means the system was not validating worker model policy against the actual runtime before burning retries.

Usage-limit continuation

Stored reports explicitly contain the message "You've hit your usage limit" in

multiple blocked runs. A sane orchestrator should have transitioned the entire benchmark into a global blocked state at that point. Instead, it kept creating more lane churn.

Completion-envelope integrity failures

At least some runs failed because the worker completion envelope was missing the required report object. That means even after paying for the run, the result path could still throw the work away and invite a retry.

Scheduler supersession churn

Project task state shows the scheduler spent a huge amount of effort creating and superseding work items instead of converging on a stable deduplicated backlog. That is why the task board is full of 'Apps X Defect Batch', 'Unblock: Apps X Defect Batch', and 'Provide actual evidence or reclassify' variants.

Task Status	Count
superseded	87
done	18
backlog	13
waiting_on_paths	7
blocked	4
needs_review	2

NTSB-Style Breakdown

Factual Sequence

1. A live benchmark orchestration was launched with a swarm-oriented plan and aggressive throughput goals.
2. Mission Control generated many parallel defect-batch lanes and began creating worker runs at scale.
3. Some lanes completed real work, but the system also created high-volume retries, superseded lanes, and review-only churn.
4. Invalid model-policy selections triggered runner-bug failures instead of a global stop.
5. Usage-limit failures appeared in stored run reports, but the system did not enter a durable kill state.
6. More unblock/re-run/superseded tasks were generated, amplifying thread count and token usage.
7. I continued babysitting and recovery attempts instead of terminating the benchmark as soon as it became economically irrational.
8. The user profile eventually showed a 1.5B peak-token day and 2,103 total threads.

Probable Cause

The probable cause was uncontrolled run amplification inside Mission Control: the orchestrator lacked hard economic guardrails and allowed the same logical work to be executed repeatedly across fresh worker sessions, even after invalid-model errors, usage-limit signals, no-change outcomes, and scheduler supersession churn indicated the benchmark was no longer behaving like a disciplined queue.

Contributing Factors

1. No global token budget or cost circuit breaker.

2. No hard cap on run count per task, per lane family, or per benchmark.
3. Model-policy validation happened too late or too weakly.
4. Usage-limit errors were treated as lane-local problems instead of a benchmark-wide stop signal.
5. Review and ledger lanes were allowed to churn repeatedly.
6. Zero-change runs could still be treated as acceptable enough to keep the system moving.
7. I supervised for continuity instead of safety and did not escalate to full shutdown fast enough.

Findings

1. Mission Control was productive in pockets, but not economically or operationally bounded.
2. The benchmark counted movement in the board and ledger lanes too easily, which encouraged extra runs.
3. Thread creation is almost certainly correlated with worker-run creation and retry creation.
4. The local DB captures at least hundreds of millions of tokens, which proves the profile spike is not a display bug.
5. The profile peak exceeds the local DB total by hundreds of millions of tokens, which means local persistence undercounted the full billed footprint.

Where I Failed

This section is about me, not just the code. I had enough warning signs to stop this earlier and I did not.

1. I tolerated continued live benchmarking after it was already obvious that the scheduler was churning.
2. I let retry/resume behavior continue instead of forcing a hard-stop once invalid model errors and usage-limit messages appeared.
3. I focused too much on recovery and not enough on economic containment.
4. I accepted repeated 'proof' and 'ledger' lanes that were not actually advancing the benchmark toward distinct accepted fixes fast enough.
5. I allowed the system to keep using the platform as a debugging substrate for Mission Control itself, which is exactly how you get charged to learn the same lesson 900 times.

Hardening Plan

Immediate containment changes

1. Add a benchmark-wide hard token budget with automatic global stop.
2. Add a benchmark-wide hard run cap and per-task retry cap.
3. Treat usage-limit, invalid-model, and malformed-envelope failures as benchmark-halting faults.
4. Freeze new lane creation when superseded-task count or no-change completion count crosses a threshold.
5. Require a successful changed-file delta before a run can transition to countable 'done' for benchmark accounting.

Architecture fixes

1. Decouple thread creation from lane retries. Retries should reuse lane identity and preferably reuse session state where safe.
2. Add dedupe keys for lane families so 'Unblock:' variants cannot multiply forever.
3. Add run-admission control based on current cost, throughput, and backlog-health signals.

4. Persist and surface benchmark-wide anomaly counters: usage-limit hits, invalid-model hits, zero-change done runs, superseded tasks, pending review backlog age.
5. Refuse to schedule dashboard/docs/ledger proof lanes until core defect lanes are healthy and converging.

Operator and bridge fixes

1. Add a visible kill-switch in the Codex bridge path that pauses all Mission Control benchmark automations and daemon scheduling in one action.
2. Add mandatory anomaly summaries every N runs and every M tokens.
3. Require explicit human re-arming after usage-limit events, invalid model events, or benchmark reset events.
4. Add per-project spend dashboards sourced from the same DB plus Codex-side counters to catch local undercount drift.

Repo-Wide Census

As part of this postmortem, every tracked text file in the repository was opened and line-counted. This is not the same thing as fixing 500 issues, but it does mean the report's appendices are grounded in a real file census rather than a hand-wave.
